SINGLE-FILE BACKUP

WHAT IT IS

Twenty-two bases and more than fifty-five thousand rows moved from a paid hosted database onto a self-hosted instance running locally. The destination product shipped its own importer; it was tested, found to corrupt records, and rejected in favour of a purpose-written migrator that handles the real edge cases - unicode in base names, reserved column names, characters the target refuses in a table title.

WHAT IT CHANGES

The vendor's own importer was verified before being trusted, and it failed

The paid account stays open until every base is checked, so nothing is stranded

Data ends up in a local file you can back up by copying a folder

Python · REST APIs · SQLite

SOMETHING LIKE THIS, FOR YOUR WORK?

The interesting part is your version of the problem.

Tell me the workflow that costs you the most time or the most trust. I will tell you honestly whether a system fixes it.
