

Voice-first agent shell

Drive your workspace by voice, with a mode that provably cannot listen.

TO KILL THE VOICE PROCESS

\$0

SPEECH STACK, FULLY LOCAL

WHAT IT IS

A standalone voice interface over the same workspace: a three-tier intent router that recognises anchored commands before it ever guesses, dictation straight into a live terminal, and a destructive-command check that requires a spoken or typed confirmation. The mode toggle is the design centrepiece - in silent mode the voice process is killed, not muted, so a shared office can verify it in the task manager.

WHAT IT CHANGES

No fuzzy execution: an unrecognised command suggests, it never runs

Silent mode is verifiable rather than promised

Speech and text both flow through one route function, so behaviour cannot diverge

Python · local STT and TTS · WebSockets · HUD

SOMETHING LIKE THIS, FOR YOUR WORK?

The interesting part is your version of the problem.

Tell me the workflow that costs you the most time or the most trust. I will tell you honestly whether a system fixes it.
